Goals

- Conceive and simulate genetic data under competing demographic scenarios
- Understand deep learning background and how a CNN works
- Use CNN to detect regions with selective sweeps on real genomes
- How to use deep learning to compare demographic scenarios

Program

Part I: The building blocks of a CNN script

The diagram illustrates the building blocks of a CNN script. It starts with an 'Input Patch' of size 28x28. This is followed by a 'Conv' layer with a 5x5 kernel, resulting in 20 feature maps. A 'Max Pool' layer with a 2x2 kernel is applied, resulting in 20 feature maps. This is followed by another 'Conv' layer with a 5x5 kernel, resulting in 50 feature maps. A 'Max Pool' layer with a 2x2 kernel is applied, resulting in 50 feature maps. This is followed by a 'Fully Connected' layer with 500 units. The final output is passed through a 'ReLU' activation function.

- **Practical Exercise 1:**

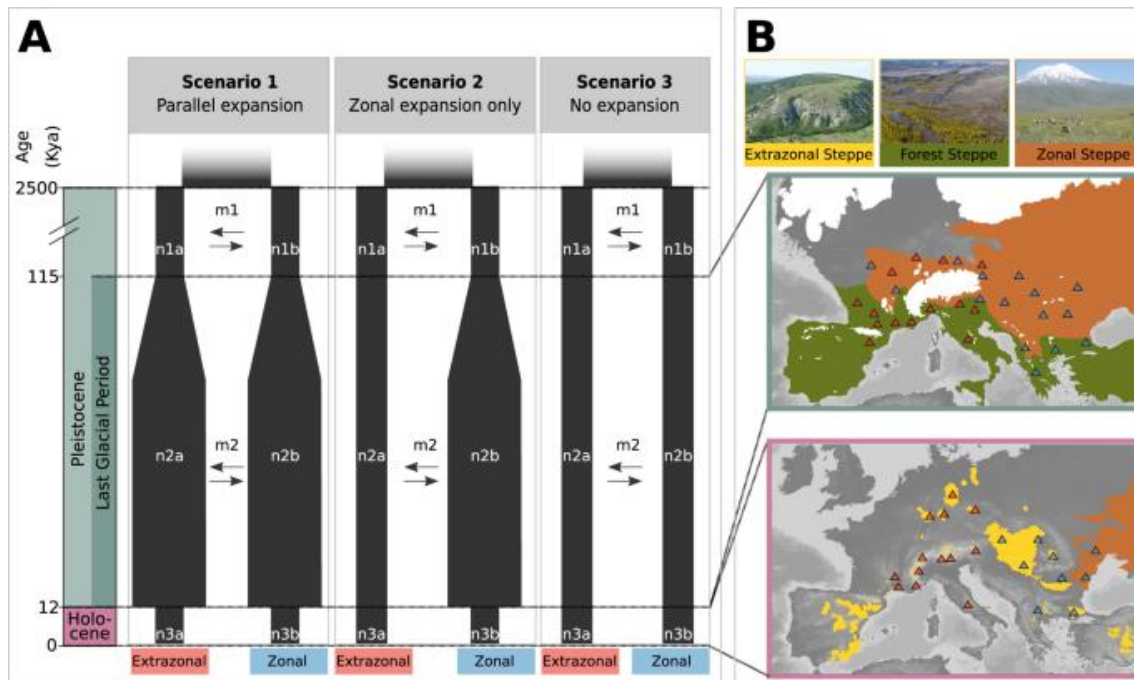

- Go through Section 1 of the Part1 script (Demographic models) and try to recognize all the elements of the network. Do you remember the function of each of those elements? Remember that you can add annotations to the code using `#` and add information that might help you when you get back to the script in the future.
- Now run all the cells until you reach the end of section 2. Your network will be training, so now we will have some time to discuss and do a quick review on the CNN elements.

```
# Define parameters for the CNN run.
batch_size = 200
### how much iterations to train the network
epochs = 100

###n of models
num_classes = 3
```

CNN Script

<https://jerryan.medium.com/batch-size-a15958708a6>

CNN Script

```
# Define the CNN architecture.
def create_cnn(xtest):
    inputShape = (xtest.shape[1], xtest.shape[2])
    ## image size. images need to have EXACTLY the same size
    inputs = Input(shape=inputShape)
    x = inputs
    ## 1D convolution - less computational intensive and also treats snps as independent;
    x = Conv1D(250, kernel_size=2, activation='relu', input_shape=(xtest.shape[1], xtest.shape[2]))(x)
    ### Enables the network to learn more complex features / shapes.
    x = AveragePooling1D(pool_size=2)(x)
    x = BatchNormalization()(x)
```

ReLU

$$\frac{df}{du} = 0$$

$$\frac{df}{du} = 1$$

```

### Linearising the image as in the initial step. From this point on the network behaves as a Multi-L
x = Flatten()(x)
x = Dense(125, activation='relu',kernel_regularizer=l2(1e-3), bias_regularizer=l2(1e-3))(x)
x = Dropout(0.5)(x)
x = Dense(125, activation='relu',kernel_regularizer=l2(1e-3), bias_regularizer=l2(1e-3))(x)
x = Dropout(0.5)(x)
x = Dense(num_classes, activation="softmax")(x)

```

Regularization

Options:

(a) Standard Neural Net

(b) After applying dropout.

CNN Script

```
# Compile the CNN.
model.compile(loss=keras.losses.categorical_crossentropy,
              optimizer='Adam',
              metrics=['accuracy'])

# We will use early stopping and save the model with the best val_accuracy.
earlyStopping = EarlyStopping(monitor='val_accuracy', patience=150, verbose=0, mode='max', restore_best_weights=True)
### stop training when validation increases error
```

Optimizer Comparison

- Practical Exercise 2:

Now open the Part 2 script. It uses Matteo's software (ImaGene) that is a CNN approach to infer selection at the LCT locus.

It uses a "simulation-on-the-fly"-like approach: training data is continuously generated by simulations to avoid the network to see the same data twice and therefore to reduce overfitting. This is a valuable consideration since, when reliable simulators are available, we have access to theoretically infinite training data, the latter being constrained by computing time only.

There are also functions to automate some of the steps we did in the previous example. You can compare the strategies and the architectures adopted.

Part II: Quick overview of other applications and future perspectives.
